attempt error correction

#### An expression grammar in BNF

Simple expressions with numbers and identifiers

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

- To derive a word/sentence from a BNF, we start with the goal variable
- In each derivation step, we replace a variable with the right hand side of one of its rules
- <u>leftmost derivation</u>: choose the leftmost variable in each step
- rightmost derivation: choose the rightmost variable in each step
- <u>parsing</u> is the discovery of a derivation: given a sentence, find a derivation from the goal variable that produces this sentence

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

- We write α, β, γ for (possibly empty) strings of terminal symbols and variables
- If *N* is a variable and  $N ::= \beta$  is a rule for *N*, then we write  $\alpha N \gamma \Rightarrow \alpha \beta \gamma$  for a single derivation step
- We write α ⇒\* β if there is a (possibly empty) sequence of derivation steps from α to β

(日) (日) (日) (日) (日) (日) (日)

 We write α ⇒<sup>+</sup> β if there is a non-empty sequence of derivation steps from α to β

#### Compare leftmost derivation with rightmost derivation

#### **G-ETF**

Enforces precedence

#### Only one possible derivation

(ロ)、(型)、(E)、(E)、 E、のQの

If a grammar has more than one derivation for a single sentence, then it is ambiguous Example:

(ロ) (同) (三) (三) (三) (○) (○)

Consider deriving the sentence:

if E1 then if E2 then S1 else S2

It has two derivations.

# May be able to eliminate ambiguities by rearranging the grammar:

This grammar generates the same language as the ambiguous grammar, but applies the common sense rule: match each else with the closest unmatched then Generally accepted resolution of this ambiguity

#### Top-down parsing

- start at the root of the derivation tree
- extend derivation by "guessing" the next production
- may require backtracking

#### Bottom-up parsing

- start at the leaves of the derivation tree
- combine tree fragments to larger fragments
- bookkeeping of successful fragments (by finite automaton)

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

### Syntax Analysis

- Recursive top-down parsing
- Nonrecursive top-down parsing

▲□▶ ▲□▶ ▲□▶ ▲□▶ = 三 のへで

Bottom-up parsing

### Approach

- Define a procedure for each syntactic variable
- The procedure for N
  - consumes token sequences derivable from N
  - has an alternative path for each rule for N
- The code for a rule  $N ::= \alpha$  consists of a code fragment for each symbol in  $\alpha$

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

- consider the symbols in  $\alpha$  from left to right
- a terminal symbol consumes the symbol
- a variable N' calls the procedure for N'

```
// <factor> ::= NUM | ID
IR factor() {
  if ( cur token == NUM ) {
    next token(); return IR NUM;
  }
  if ( cur token == ID ) {
    next token(); return IR ID;
  }
  syntax_error("NUM or ID expected");
```

▲□▶▲□▶▲□▶▲□▶ □ のQ@

### Recursive descent for G-ETF/2

```
/* <term> ::= <term> * <factor>
| <term> / <factor>
| <factor>
```

\*\*/

```
IR term() {
  if(???) {
    term(); check(MUL); factor();
    return IR MUL(...);
  }
  if(???) {
    term(); check(DIV); factor();
    return IR DIV(...);
  }
  return factor();
```

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

## Trouble with recursive descent / top-down parsing

#### Alternatives

• How do we decide on one of the productions?

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

Would it help to look at the next token?

#### Alternatives

- How do we decide on one of the productions?
- Would it help to look at the next token?

#### Left recursion

 If we choose the first or second rule, we end up in an infinite recursion without consuming input.

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

• A variable *N* in a BNF is left recursive, if there is a derivation such that  $N \Rightarrow^+ N\alpha$ , where  $\alpha$  is an arbitrary string of variables and terminals.

(日) (日) (日) (日) (日) (日) (日)

- A variable *N* in a BNF is <u>left recursive</u>, if there is a derivation such that  $N \Rightarrow^+ N\alpha$ , where  $\alpha$  is an arbitrary string of variables and terminals.
- Fact: if a BNF has a left recursive variable, then top-down parsing for this BNF may not terminate.

(日) (日) (日) (日) (日) (日) (日)

- A variable *N* in a BNF is <u>left recursive</u>, if there is a derivation such that  $N \Rightarrow^+ N\alpha$ , where  $\alpha$  is an arbitrary string of variables and terminals.
- Fact: if a BNF has a left recursive variable, then top-down parsing for this BNF may not terminate.

(日) (日) (日) (日) (日) (日) (日)

• Cure: remove left recursion by transforming the BNF

### Elimination of direct left recursion

Suppose G has a left recursive variable A with rules

$$\mathbf{A} \rightarrow \mathbf{A}\alpha_1 \mid \cdots \mid \mathbf{A}\alpha_n \mid \beta_1 \mid \cdots \mid \beta_m$$

where none of the  $\beta_i$  starts with *A* and all  $\alpha_i \neq \varepsilon$ 

- Add a new variable A'
- Remove all productions for A
- Add new productions

$$\mathbf{A} \to \beta_1 \mathbf{A}' \mid \dots \mid \beta_m \mathbf{A}'$$
$$\mathbf{A}' \to \varepsilon \mid \alpha_1 \mathbf{A}' \mid \dots \mid \alpha_n \mathbf{A}'$$

 This transformation is always possible: same language, but A no longer left recursive

#### Original grammar G-ETF

#### After elimination of left recursion

# Lookahead set for a rule

$$LA_k(A ::= \alpha) = FIRST_k(\alpha) \odot_k FOLLOW_k(A)$$

# Definition LL(k) grammar

A BNF is an LL(k) grammar, if for each variable A its rule set  $A ::= \alpha_1 \mid \cdots \mid \alpha_n$  fulfills

$$\forall i \neq j : LA_k(A ::= \alpha_i) \cap LA_k(A ::= \alpha_j) = \emptyset$$

# LL(k) Parsing

On input *w*, the parser for *A* chooses the unique right hand side  $\alpha_i$  such that  $w|_k \in LA_k(A ::= \alpha_i)$  and signals a syntax error if no such *i* exists.

# Syntax Analysis

- Recursive top-down parsing
- Nonrecursive top-down parsing

▲□▶ ▲□▶ ▲□▶ ▲□▶ = 三 のへで

Bottom-up parsing

- A top-down parser may be implemented without recursion using a pushdown automaton
- The pushdown keeps track of the terminals and variables that still need to be matched

(ロ) (同) (三) (三) (三) (○) (○)

- $Q = \{q\}$  a single state, also serves as initial state
- Σ is the input alphabet
- $\Gamma = \Sigma \cup VAR$ , the set of terminals and variables, is the pushdown alphabet
- $Z_0 = G \in VAR$ , the pushdown bottom symbol is the goal variable
- $\delta$  is defined by
  - $\delta(q,\varepsilon,A) \ni (q,\alpha)$  if  $A ::= \alpha$  is a rule
  - $\delta(q, a, a) = (q, \varepsilon)$
- In the PDA, the choice of the rule is nondeterministic, in practice we disambiguate using LL(k) grammars with lookahead

# Syntax Analysis

- Recursive top-down parsing
- Nonrecursive top-down parsing

▲□▶ ▲□▶ ▲□▶ ▲□▶ = 三 のへで

Bottom-up parsing

### Goal

Given an input string and a BNF, construct a parse tree starting at the leaves and working up to the root.

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

## Sentential form

For a BNF with start variable *S*, every  $\alpha$  such that  $S \Rightarrow^* \alpha$  is a sentential form.

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

If  $\alpha \in \Sigma^*$ , then  $\alpha$  is a sentence.

A left sentential form occurs in a left derivation.

A right sentential form occurs in a right derivation.

### Procedure:

- The bottom-up parser repeatedly matches a right-sentential form of the language against the tree's upper frontier.
- At each match, it applies a reduction to build on the frontier:
  - each reduction matches an upper frontier of the partially built tree to the RHS of some production

(日) (日) (日) (日) (日) (日) (日)

- each reduction adds a node on top of the frontier
- The final result is a rightmost derivation, in reverse.

#### Consider the BNF

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● のへぐ

### and the input string

abbcde

(Construct a rightmost derivation)

To construct a the rightmost derivation, we need to find handles.

### Handle

A <u>handle</u> is a substring  $\alpha$  of the trees frontier that matches a rule  $A ::= \alpha$  which is applied at that point in a rightmost derivation

(ロ) (同) (三) (三) (三) (○) (○)

To construct a the rightmost derivation, we need to find handles.

### Handle

A <u>handle</u> is a substring  $\alpha$  of the trees frontier that matches a rule  $A ::= \alpha$  which is applied at that point in a rightmost derivation

# Formally

- In a right-sentential form αβw, the string β is a handle for production A ::= β
- if  $S \Rightarrow_{rm}^* \alpha Aw \Rightarrow_{rm} \alpha \beta w$  then  $\beta$  is a handle for  $A ::= \beta$  in  $\alpha \beta w$

(日) (日) (日) (日) (日) (日) (日)

```
1 <qoal> ::= <expr>
2 <expr> ::= <expr> + <term>
3
             | <expr> - <term>
4
              <term>
5
 <term> ::= <term> * <factor>
6
             | <term> / <factor>
7
             <factor>
8
 <factor> ::= num
9
             | id
```

A rightmost derivation for this grammar has unique handles.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

One scheme to implement a handle-pruning, bottom-up parser is called a shift-reduce parser.

Shift-reduce parsers use a stack and an input buffer

- initialize stack with \$
- Repeat until the top of the stack is the goal symbol and the input token is \$
  - find the handle
  - if we don't have a handle on top of the stack, <u>shift</u> an input symbol onto the stack
  - prune the handle if we have a handle for A ::= β on the stack, reduce:
    - pop  $|\beta|$  symbols off the stack
    - push A onto the stack

Apply shift-reduce parsing to x-2\*y

Shift until top of stack is the right end of a handle

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

Pind the left end of the handle and reduce

A shift-reduce parser has just four canonical actions:

- shift next input symbol is shifted onto the top of the stack
- reduce right end of handle is on top of stack; locate left end of handle within the stack; pop handle off stack and push appropriate non-terminal LHS

(ロ) (同) (三) (三) (三) (○) (○)

- accept terminate parsing and signal success
- error call an error recovery routine

But how do we know

- that there is a complete handle on the stack?
- which handle to use?

### Recognize handles with a DFA [Knuth 1965]

DFA transitions shift states instead of symbols

< □ > < 同 > < Ξ > < Ξ > < Ξ > < Ξ < </p>

accepting states trigger reductions

# Skeleton for LR parsing

```
push s0
token \leftarrow next token()
while(true)
  s \leftarrow top of stack
  if action[s,token] = SHIFT(si) then
    push si
    token \leftarrow next token()
  else if action[s,token] = REDUCE(A ::= \beta) then
    pop |\beta| states
    s' \leftarrow \text{top of stack}
    push goto[s', A]
  else if action[s, token] = ACCEPT then
    return
  else error()
```

 Accepting a sentence takes k shifts, / reduces, and 1 accept, where k is the length of the input string and / is the length of the rightmost derivation

# Example tables

| state | ACTION     |            |            | GOTO       |   |   |   |

Start with Stack \$ 0 Input id \* id + id \$

#### A BNF is LR(k) if

$$S \Rightarrow_{rm}^{*} \alpha Aw \Rightarrow_{rm} \alpha \beta w$$

and

$$S \Rightarrow_{rm}^* \gamma B x \Rightarrow_{rm} \alpha \beta y$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

and

$$w|_k = y|_k$$

implies that  $\alpha Ay = \gamma Bx$ .

- almost all context-free programming language constructs can be expressed naturally with an LR(1) grammar
- LR grammars are the most general grammar that can be parsed by a deterministic bottom-up parser
- LR(1) grammars have efficient parsers
- LR parsers detect errors as early as possible
- LR grammars are more general: Every LL(k) grammar is also a LR(k) grammar

(日) (日) (日) (日) (日) (日) (日)

LR(1) — not useful in practice because tables are too big

(日) (日) (日) (日) (日) (日) (日)

- all deterministic languages have LR(1) grammar
- very large tables
- slow construction
- SLR(1)
  - smallest class of grammars
  - smallest tables
  - simple, fast construction
- LALR(1)
  - expressivity between SLR(1) and LR(1)
  - same number of states as SLR(1)
  - clever algorithm yields fast construction

Parser states are modeled with LR(k) items.

#### Definition

An <u>LR(k) item</u> is a pair  $[A \rightarrow \alpha \bullet \beta, w]$  where

- A → αβ is a rule; the can divide the right hand side arbitrarily; intution: how much of the right hand side has been seen already
- w is a lookahead string containing at most k symbols

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

Parser states are modeled with LR(k) items.

#### Definition

An <u>LR(k) item</u> is a pair  $[A \rightarrow \alpha \bullet \beta, w]$  where

- A → αβ is a rule; the can divide the right hand side arbitrarily; intution: how much of the right hand side has been seen already
- w is a lookahead string containing at most k symbols

#### Cases of interest

- k = 0: LR(0) items play a role in SLR(1) construction
- k = 1: LR(1) items are used for constructing LR(1) and LALR(1) parsers

Consider LR(0) items without lookahead

- [A → •aBC] indicates that the parser is now looking for input derived from aBC
- [A → aB C] indicates that input derived from aB has been seen, now looking for something derived from C

< □ > < 同 > < Ξ > < Ξ > < Ξ > < Ξ < </p>

There are four items associated with  $A \rightarrow aBC$ 

The CFSM for a grammar is a DFA which recognizes viable prefixes of right-sentential forms:

A <u>viable prefix</u> is any prefix that does not extend beyond the handle.

The CFSM accepts when a handle has been discovered and needs to be reduced.

A state of the CFSM is a set of items.

To construct the CFSM we need two functions wherer I is a set of items and X is a grammar symbol:

- closure0(*I*) to build its states
- goto0(*I*, *X*) to determine its transitions

The closure of an item  $[A \rightarrow \alpha \bullet B\beta$  contains the item itself and any other item that can generate legal strings following  $\alpha$ . Thus if the parser has a viable prefix  $\alpha$  on the stack, the remaining input should be derivable from  $B\beta$ .

#### Closure0

For a set *I* of LR(0) items, the set closureO(*I*) is the smallest set such that

() 
$$I \subseteq closure(I)$$

**Implementation:** start with first rule, repeat second rule until no further items can be added.

Let *I* be a set of LR(0) items and *X* be a grammar symbol.

$$\texttt{goto0}(I, X) = \texttt{closure0}(\{[A \to \alpha X \bullet \beta] \mid [A \to \alpha \bullet X \beta] \in I)$$

If *I* is the set of items for a viable prefix  $\gamma \alpha$ , then goto0(*I*, *X*) is the set of items for viable prefix  $\gamma \alpha X$ . Accepting states of the CFSM: *I* is accepting if it contains a reduce item of the form  $[A \rightarrow \alpha \bullet]$ .

New start item  $[S' 
ightarrow \bullet S \$]$ , where

- S' is a new start symbol that does not occur on any RHS
- S is the previous start symbol
- \$ marks the end of input

Compute the set of states  $\ensuremath{\mathcal{S}}$  where each state is a set of items

(日) (日) (日) (日) (日) (日) (日)

```
function items (G + S')
   I \leftarrow \text{closure0}(\{[S' \rightarrow \bullet S\$]\})
   \mathcal{S} \leftarrow \{I\}
   \mathcal{W} \leftarrow \{I\}
   while \mathcal{W} \neq \emptyset
       remove some I from \mathcal{W}
       for each grammar symbol X
           let I' \leftarrow \text{qoto}(I, X)
           if l' \neq \emptyset and l' \notin S then
               add I' to {\mathcal W} and {\mathcal S}
   return S
```

## Construction of the LR(0) parse table

Output: tables ACTION and GOTO
① Let {I<sub>0</sub>, I<sub>1</sub>,...} = items(G)

State i of the CFSM corresponds to item I<sub>i</sub>

- if  $[A \rightarrow \alpha \bullet a\beta] \in I_i$ ,  $a \in \Sigma$  and  $goto0(I_i, a) = I_j$ then ACTION[i, a] = SHIFT j
- If [A → α•] ∈ I<sub>i</sub> and A ≠ S' then ACTION[i, a] = REDUCE A → α, for all a
- If [S' → S\$•] ∈ I<sub>i</sub> then ACTION[i, a] = ACCEPT, for all a
- If  $gotol(I_i, A) = I_j$  for variable A then GOTO[i, A] = j
- set all undefined entries in ACTION and GOTO to ERROR
- initial state of parser corresponds to  $I_0 = closure0(\{[S' \rightarrow \bullet S\$]\})$

# Example ACTION table

▲□▶▲圖▶▲≣▶▲≣▶ ≣ のQ@

- If there are multiply defined entries in the *ACTION* table, then the grammar is not LR(0).
- There are two kinds of conflict
  - shift-reduce: shift and reduce are possible in the same item set
  - reduce-reduce: two different reduce actions are possible in the same item set

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

- Examples
  - $\mathbf{A} \to \varepsilon \mid \mathbf{a} \alpha$

on input *a*, shift *a* or reduce  $A \rightarrow \varepsilon$ ?

- a = b+c\*d with expression grammar after reading c, should we shift or reduce?
- Use lookahead to resolve conflicts

# SLR(1) — simple lookahead LR

Add lookahead after computing the LR(0) item sets

• Let 
$$\{I_0, I_1, \dots\} = \texttt{items}(G)$$

State i of the CFSM corresponds to item I<sub>i</sub>

- if  $[A \rightarrow \alpha \bullet a\beta] \in I_i$ , for  $a \neq \$$  and  $goto0(I_i, a) = I_j$ then ACTION[i, a] = SHIFT j
- If  $[A \rightarrow \alpha \bullet] \in I_i$  and  $A \neq S'$ then  $ACTION[i, a] = \text{REDUCE } A \rightarrow \alpha$ , for all  $a \in FOLLOW(A)$
- If [S' → S \$] ∈ I<sub>i</sub> then ACTION[i, \$] = ACCEPT
- If  $gotol(I_i, A) = I_j$  for variable A then GOTO[i, A] = j
- set all undefined entries in ACTION and GOTO to ERROR

• initial state of parser corresponds to  $I_0 = closure0(\{[S' \rightarrow \bullet S\$]\})$ 

- Items of the form  $[A \rightarrow \alpha \bullet \beta, a]$  for  $a \in \Sigma$
- Propagate lookahead in construction to choose the correct reduction

< □ > < 同 > < Ξ > < Ξ > < Ξ > < Ξ < </p>

- Lookahead has only effect on reduce items
- We can decide between reductions  $[A \rightarrow \alpha \bullet, a]$  and  $[B \rightarrow \alpha \bullet, b]$  by examining the lookahead.

#### Closure1

For a set *I* of LR(1) items, the set closure1(*I*) is the smallest set such that

- $I \subseteq closure1(I)$
- If [A →  $\alpha \bullet B\beta$ , a] ∈ closure0(I) then [B → • $\gamma$ , b] ∈ closure0(I), for all rules B →  $\gamma$  and for all b ∈ FIRST<sub>1</sub>( $\beta$ a).

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

#### Let *I* be a set of LR(1) items and *X* be a grammar symbol.

$$\texttt{gotol}(\textit{\textbf{I}},\textit{\textbf{X}}) = \texttt{closurel}(\{[\textit{\textbf{A}} \rightarrow \alpha\textit{\textbf{X}} \bullet \beta,\textit{\textbf{a}}] \mid [\textit{\textbf{A}} \rightarrow \alpha \bullet \textit{\textbf{X}}\beta,\textit{\textbf{a}}] \in \textit{\textbf{I}}\}$$

#### Construction of the CFSM

as before

▲□▶▲□▶▲□▶▲□▶ ▲□ ● ● ●

## Construction of the LR(1) parse table

Output: tables ACTION and GOTO
Let {I<sub>0</sub>, I<sub>1</sub>,...} = items(G)
State *i* of the CFSM corresponds to item I<sub>i</sub>
if [A → α • aβ, b] ∈ I<sub>i</sub>, a ≠ \$ and goto1(I<sub>i</sub>, a) = I<sub>j</sub> then ACTION[i, a] = SHIFT j
If [A → α•, b] ∈ I<sub>i</sub> and A ≠ S' then ACTION[i, b] = REDUCE A → α
If [S' → S•, \$] ∈ I<sub>i</sub> then ACTION[i, \$] = ACCEPT

- If  $gotol(I_i, A) = I_j$  for variable A then GOTO[i, A] = j
- set all undefined entries in ACTION and GOTO to ERROR
- initial state of parser corresponds to  $I_0 = closure1(\{[S' \rightarrow \bullet S, \$]\})$

The <u>core</u> of a set of LR(1) items is the set of LR(0) items obtained by stripping off all lookahead. The following two sets have the same core:

• {[
$$\boldsymbol{A} \to \boldsymbol{\alpha} \bullet \boldsymbol{\beta}, \boldsymbol{a}$$
], [ $\boldsymbol{A} \to \boldsymbol{\alpha} \bullet \boldsymbol{\beta}, \boldsymbol{c}$ ]}

• {[
$$\boldsymbol{A} \rightarrow \boldsymbol{\alpha} \bullet \boldsymbol{\beta}, \boldsymbol{b}$$
], [ $\boldsymbol{A} \rightarrow \boldsymbol{\alpha} \bullet \boldsymbol{\beta}, \boldsymbol{c}$ ]}

#### Key idea

If two LR(1) item sets have the same core, then we can merge their states in the ACTION and GOTO tables.

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

Compared to LR(1) we need a single new step:

For each core present among the set of LR(1) items, find all sets having that core and replace these sets by their union.

The goto function must be updated to reflect the replacement sets.

The resulting algorithm is very expensive. There is a more efficient algorithm that analyses the LR(0) CFSM.

(ロ) (同) (三) (三) (三) (○) (○)

Precedence and associativity can be used to resolve shift-reduce conflicts in ambiguous grammars.

• lookahead symbol has higher precedence  $\Rightarrow$  shift

(日) (日) (日) (日) (日) (日) (日)

• same precedence, left associative  $\Rightarrow$  reduce

Advantages:

- more concise, albeit ambiguous, grammars
- shallower parse trees  $\Rightarrow$  fewer reductions
- Classic application: expression grammars

# With precedence and associativity we can use a very simple expression grammar without useless productions.

$$E 
ightarrow E * E \mid E/E \mid E + E \mid E - E \mid (E) \mid -E \mid d \mid num$$

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ● ● ● ● ●

#### **Right recursion**

required in top-down parsers for termination

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

- more stack space
- right-associative operators

#### Left recursion

- works fine in bottom-up parsers
- Iimits required stack
- left associative operators
