--- This Lecture ---

▶ Execution observation
  ▶ With logging
  ▶ Using debuggers
▶ Tracking causes and effects
The Main Steps in Systematic Debugging

Reproduce failure with test input
The Main Steps in Systematic Debugging

Program State

Time

Reduction of failure-inducing problem
The Main Steps in Systematic Debugging

Program State

State known to be healthy
The Main Steps in Systematic Debugging

State known to be infected

Program State

Time

earliest state known to be infected
latest state known to be healthy
The Main Steps in Systematic Debugging

Program State

State where failure becomes observable
The Main Steps in Systematic Debugging

- Separate healthy from infected states

Program State

- Latest state known to be healthy
- Earliest state known to be infected
The Main Steps in Systematic Debugging

- Separate healthy from infected states
- Separate relevant from irrelevant states
Central Problem

How can we observe a program run?
Central Problem

How can we observe a program run?

Challenges/Obstacles

- Observation of intermediate state not part of functionality
- Observation can change the behavior
- Narrowing down to relevant time/state sections
The Naive Approach: Print Logging

Println Debugging
Manually add print statements at code locations to be observed
System.out.println("size=\t"+ size);
The Naive Approach: Print Logging

Println Debugging
Manually add print statements at code locations to be observed

```java
System.out.println("size = " + size);
```

- ✔ Simple and easy
- ✔ Can use any output channel
- ✔ No tools or infrastructure needed, works on any platform
The Naive Approach: Print Logging

Println Debugging
Manually add print statements at code locations to be observed
System.out.println("size\n=\n"+ size);

✓ Simple and easy
✓ Can use any output channel
✓ No tools or infrastructure needed, works on any platform

✗ Code cluttering
✗ Output cluttering (at least need to use debug channel)
✗ Performance penalty, possibly changed behavior (timing, . . . )
✗ Buffered output lost on crash
✗ Source code required, recompilation necessary
Example (Logging Framework for Java)

java.util.logging

Main principles of Java logging

- Each class can have its own Logger object
- Each logger is associated with a level and a handler
- Levels: FINEST < FINER < FINE < CONFIG < INFO < WARNING < SEVERE
- Handlers: j.u.l.ConsoleHandler, j.u.l.FileHandler
- Example: log message with myLogger and level INFO:
  myLogger.info(Object message);
- Logging can be controlled by program or properties file:
  which logger, level, filter, formatting, handler, etc.
- No recompilation necessary for reconfiguration
Logging Demo
Evaluation of Logging Frameworks

- Output cluttering can be mastered
- Small performance overhead
- Exceptions are loggable
- Log complete up to crash
- Instrumented source code reconfigurable w/o recompilation

- Code cluttering — don’t try to log everything!

Code cluttering avoidable with aspects, but also with Debuggers
What is a Debugger?

Basic Functionality of a Debugger

Execution Control  Stop execution on specified conditions: breakpoints

Interpretation  Step-wise execution of code

State Inspection  Observe value of variables and stack

State Change  Change state of stopped program

Historical term Debugger is misnomer as there are many debugging tools
What is a Debugger?

Basic Functionality of a Debugger

**Execution Control** Stop execution on specified conditions: breakpoints

**Interpretation** Step-wise execution of code

**State Inspection** Observe value of variables and stack

**State Change** Change state of stopped program

Historical term Debugger is misnomer as there are many debugging tools

- Traditional debuggers (gdb for C) based on command line I/F
- We use the built-in GUI-based debugger of the Eclipse framework
  - Feel free to experiment with other debuggers!
public static int search(int[] array, int target) {
    int low = 0;
    int high = array.length;
    int mid;
    while (low <= high) {
        mid = (low + high) / 2;
        if (target < array[mid]) {
            high = mid - 1;
        } else if (target > array[mid]) {
            low = mid + 1;
        } else {
            return mid;
        }
    }
    return -1;
}
Eclipse Debugger

- Open directory BinSearch, create project Search
- Create/show run configuration testBin1
- Run testBin1
- Open Debugging view of project Search
Running a few test cases . . .

search( {1,2}, 1 ) == 0 ✔
Running a few test cases . . .

search( {1,2}, 1 ) == 0 ✓
search( {1,2}, 2 ) == 1 ✓
Running a few test cases ... 

search( {1,2},  1 ) == 0 ✓
search( {1,2},  2 ) == 1 ✓
search( {1,2},  4 ) throws
ArrayIndexOutOfBoundsException:  3 ✗
Running a few test cases ...

```
search( {1,2}, 1 ) == 0 ✔
search( {1,2}, 2 ) == 1 ✔
search( {1,2}, 4 ) throws
ArrayIndexOutOfBoundsException: 3 ❌
```

Example taken from a published JAVA text book :-(

Testing
Halting Program Execution

Breakpoint
A program location that, when it is reached, halts execution

Example (Setting Breakpoint)
In `search()` at loop, right-click, toggle breakpoint

Some remarks on breakpoints
- Set breakpoint at last statement where state is known to be healthy
- Formulate healthiness as an explicit hypothesis
- In Eclipse, not all lines can be breakpoints, because these are actually inserted into bytecode
- Remove breakpoints when no longer needed
Example (Execution Control Commands)

- **Start** debugging of run configuration testBin1
- **Resume** halts when breakpoint is reached in next loop execution
- **Disable** breakpoint for this session
- **Resume** executes now until end
- **Remove** from debug log (Remove All Terminated)
- **Enable** breakpoint again in Breakpoints window
- **Close** debugging perspective
Step-Wise Execution of Programs

Step-Wise Execution Commands

- **Step Into** Execute next statement, then halt
- **Step Over** Consider method call as one statement

Some remarks on step-wise execution

- Usually Java library methods stepped over
  - They should not contain defects
  - You probably don’t have the source code
- To step over bigger chunks, change breakpoints, then resume
Inspecting the Program State

Inspection of state while program is halted

- Variables window
  - Unfold reference types
  - Pretty-printed in lower half of window
- Tooltips for variables in focus in editor window
- Recently changed variables are highlighted

Example (Tracking `search()`)

- Start debugging at beginning of loop (\texttt{testBin2})
- Step through one execution of loop body
- After first execution of loop body, \texttt{low==high==2}
- Therefore, \texttt{mid==2}, but \texttt{array[2]} doesn't exist!
- If \texttt{target} is greater than all array elements, eventually \texttt{low==mid==array.length}
Inspecting the Program State

**Inspection of state while program is halted**
- **Variables window**
  - Unfold reference types
  - Pretty-printed in lower half of window
- **Tooltips for variables in focus in editor window**
- **Recently changed variables are highlighted**

**Example (Tracking search())**
- Start debugging at beginning of loop (testBin2)
- Step through one execution of loop body
- After first execution of loop body  low==high==2
- Therefore, mid==2, but array[2] doesn't exist!
- If target is greater than all array elements, eventually  low==mid==array.length
Changing the Program State

Hypothesis for Correct Value

Variable `high` should have value `array.length-1`
Hypothesis for Correct Value

Variable `high` should have value `array.length-1`

Changing state while program is halted

- Right-click on identifier in Variables window, Change Value
Changing the Program State

Hypothesis for Correct Value
Variable high should have value array.length-1

Changing state while program is halted
- Right-click on identifier in Variables window, Change Value

Example (Fixing the defect in the current run)
At start of second round of loop, set high to correct value 1
Resuming execution now yields correct result
Halting Execution upon Specific Conditions

Use Boolean Watch expression in conditional breakpoint
Watching States with **Debuggers**

**Halting Execution upon Specific Conditions**
Use Boolean **Watch** expression in **conditional breakpoint**

---

**Example (Halting just before exception is thrown)**

- From test run: argument \( \text{mid} \) of \( \text{array} \) is 2 at this point
- Create breakpoint at code position where evaluation takes place
- Add watch expression \( \text{mid==2} \) to breakpoint properties
- Disable breakpoint at start of loop
- Execution halts exactly when \( \text{mid==2} \) becomes \text{true}
Watching States with Debuggers

**Halting Execution upon Specific Conditions**

Use Boolean Watch expression in conditional breakpoint

Example (Halting just before exception is thrown)

- From test run: argument mid of array is 2 at this point
- Create breakpoint at code position where evaluation takes place
- Add watch expression mid==2 to breakpoint properties
- Disable breakpoint at start of loop
- Execution halts exactly when mid==2 becomes true

**Hints on watch expressions**

- Make sure scope of variables in watch expressions is big enough
Evaluation of Debuggers

✓ Code cluttering completely avoided
✓ Prudent usage of breakpoints/watches reduces states to be inspected
✓ Full control over all execution aspects

✗ Debuggers are interactive tools, re-use difficult
✗ Performance can degrade, disable unused watches
✗ Inspection of reference types (lists, etc.) is tedious
Evaluation of Debuggers

- Code cluttering completely avoided
- Prudent usage of breakpoints/watches reduces states to be inspected
- Full control over all execution aspects

- Debuggers are interactive tools, re-use difficult
- Performance can degrade, disable unused watches
- Inspection of reference types (lists, etc.) is tedious

Important Lessons

- Both, logging and debuggers are necessary and complementary
- Need visualization tools to render complex data structures
- Minimal/small input, localisation of unit is important
Tracking Causes and Effects

Determine defect that is origin of failure

Fundamental problem
Program executes forward, but need to reason backwards from failure

Example
In search() the failure was caused by wrong value mid, but the real culprit was high
Effects of Statements

Fundamental ways how statements may affect each other

**Write**  Change the program state
Assign a new value to a variable read by another statement

**Control**  Change the program counter
Determine which statement is executed next
Effects of Statements

Fundamental ways how statements may affect each other

**Write**  Change the program state
Assign a new value to a variable read by another statement

**Control**  Change the program counter
Determine which statement is executed next

Statements with **Write** Effect (in **Java**)

- Assignments
- I/O, because it affects buffer content
- `new()`, because object initialisation writes to fields
### Effects of Statements

**Fundamental ways how statements may affect each other**

<table>
<thead>
<tr>
<th><strong>Write</strong></th>
<th>Change the program state</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Assign a new value to a variable read by another statement</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Control</strong></th>
<th>Change the program counter</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Determine which statement is executed next</td>
</tr>
</tbody>
</table>

**Statements with Control Effect (in Java)**

- **Conditionals, switches**
- **Loops**: determine whether their body is executed
- **Dynamic method calls**: implicit case distinction on implementations
- **Abrupt termination statements**: `break`, `return`
- **Exceptions**: potentially at each object or array access!
Statement Dependencies

Definition (Data Dependency)

Statement B is data dependent on statement A iff

1. A writes to a variable v that is read by B and
2. There is at least one execution path between A and B in which v is not written to

“The outcome of A can directly influence a variable read in B”
Statement Dependencies

Definition (Control Dependency)

Statement B is control dependent on statement A iff

- There is an execution path from A to B such that:
  For all statements $S \neq A$ on the path, all execution paths from $S$ to the method exit pass through B
  and
- There is an execution path from A to the method exit that does not pass through B

“The outcome of A can influence whether B is executed”
```c
int low = 0;
int high = array.length;
int mid;
while ( low <= high ) {
    mid = (low + high)/2;
    if ( target < array[mid] ) {
        high = mid - 1;
    } else if ( target > array[mid] ) {
        low = mid + 1;
    } else {
        return mid;
    }
}
return -1;
```
Example

int low = 0;
int high = array.length;
int mid;
while ( low <= high ) {
    mid = (low + high)/2;
    if ( target < array[mid] ) {
        high = mid - 1;
    } else if ( target > array[mid] ) {
        low = mid + 1;
    } else {
        return mid;
    }
}
return -1;

mid is data-dependent on this statement
Example

1 int low = 0;
2 int high = array.length;
3 int mid;
4 while ( low <= high ) {
5   mid = (low + high)/2;
6   if ( target < array[ mid ] ) {
7     high = mid - 1;
8   } else if ( target > array[ mid ] ) {
9     low = mid + 1;
10  } else {
11    return mid;
12  }
13 }
14 return -1;

mid is control-dependent on the while statement
Definition (Backward Dependency)

Statement B is **backward dependent** on statement A iff there is a sequence of statements $A = A_1, A_2, \ldots, A_n = B$ such that:

1. for all $i$, $A_{i+1}$ is either control dependent or data dependent on $A_i$

2. there is at least one $i$ with $A_{i+1}$ being data dependent on $A_i$

“The outcome of $A$ can influence the program state in $B$”
```java
int low = 0;
int high = array.length;
int mid;
while ( low <= high ) {
    mid = (low + high)/2;
    if ( target < array[mid] ) {
        high = mid - 1;
    } else if ( target > array[mid] ) {
        low = mid + 1;
    } else {
        return mid;
    }
}
return -1;
```
Example

```java
int low = 0;
int high = array.length;
int mid;
while ( low <= high ) {
    mid = (low + high)/2;
    if ( target < array[mid] ) {
        high = mid - 1;
    } else if ( target > array[mid] ) {
        low = mid + 1;
    } else {
        return mid;
    }
}
return -1;
```

`mid` is backward-dependent on data- and control-dependent statements.
Example

```java
int low = 0;
int high = array.length;
int mid;
while (low <= high) {
    mid = (low + high)/2;
    if (target < array[mid]) {
        high = mid - 1;
    } else if (target > array[mid]) {
        low = mid + 1;
    } else {
        return mid;
    }
}
return -1;
```

`mid` is backward-dependent on data- and control-dependent statements.
Example

```java
int low = 0;
int high = array.length;
int mid;
while ( low <= high ) {
    mid = (low + high)/2;
    if ( target < array[mid] ) {
        high = mid - 1;
    } else if ( target > array[mid] ) {
        low = mid + 1;
    } else {
        return mid;
    }
}
return -1;
```

Backward-dependent statements for **first** execution of loop body
Example

```java
1 int low = 0;
2 int high = array.length;
3 int mid;
4 while ( low <= high ) {
5     mid = (low + high)/2;
6     if ( target < array[mid] ) {
7         high = mid - 1;
8     } else if ( target > array[mid] ) {
9         low = mid + 1;
10     } else {
11         return mid;
12     }
13 }
14 return -1;
```

Backward-dependent statements for repeated execution of loop body
Separate healthy from infected states
Separate relevant from irrelevant states
Separate healthy from infected states
Separate relevant from irrelevant states
Systematic Location of Defects

- Separate healthy from infected states
- Separate relevant from irrelevant states
- Compute backward-dependent statements from infected locations
Tracking Down Infections

Algorithm for systematic location of defects

Let \( \mathcal{I} \) be a set of infected locations (variable+program counter)

1. Initialize \( \mathcal{I} := \{ \text{infected location reported by failure} \} \)
2. Choose a current, infected location \( L \in \mathcal{I} \)
3. Compute statements \( S \) that may contain origin of defect: one level of backward dependency from \( L \) in execution path
4. Inspect variables \( v_1, \ldots, v_n \) written to in \( S \):
   let \( \mathcal{M} \subseteq \{ v_1, \ldots, v_n \} \) be the infected variables
5. If \( \mathcal{M} \neq \emptyset \) (there is an infected variable):
   5.1 Let \( \mathcal{I} := (\mathcal{I} \setminus \{L\}) \cup \mathcal{M} \times S \) (replace \( L \) with new candidates in \( \mathcal{M} \))
   5.2 Goto 2.
6. \( L \) depends only on healthy locations, it must be the infection site!
Example

```java
int low = 0;
int high = array.length;
int mid;
while ( low <= high ) {
    mid = (low + high)/2;
    if ( target < array[mid] ) {
        high = mid - 1;
    } else if ( target > array[mid] ) {
        low = mid + 1;
    } else {
        return mid;
    }
}
return -1;
```

mid is infected, mid==low==high==2
```java
int low = 0;
int high = array.length;
int mid;
while ( low <= high ) {
    mid = (low + high)/2;
    if ( target < array[mid] ) {
        high = mid - 1;
    } else if ( target > array[mid] ) {
        low = mid + 1;
    } else {
        return mid;
    }
}
return -1;
```

Look for origins of `low` and `high`
Example

```java
int low = 0;
int high = array.length;
int mid;

while ( low <= high ) {
    mid = (low + high)/2;
    if ( target < array[mid] ) {
        high = mid - 1;
    } else if ( target > array[mid] ) {
        low = mid + 1;
    } else {
        return mid;
    }
}
return -1;
```

`low` was changed in previous loop execution, value low==1 seems healthy.
```java
int low = 0;
int high = array.length;
int mid;

while ( low <= high ) {
    mid = (low + high)/2;
    if ( target < array[mid] ) {
        high = mid - 1;
    } else if ( target > array[mid] ) {
        low = mid + 1;
    } else {
        return mid;
    }
}
return -1;
```

`high == 2` set at start (if-branch not taken when target not found), infected!
```java
int low = 0;
int high = array.length;
int mid;
while ( low <= high ) {
    mid = (low + high)/2;
    if ( target < array[mid] ) {
        high = mid - 1;
    } else if ( target > array[mid] ) {
        low = mid + 1;
    } else {
        return mid;
    }
}
return -1;
```

*high* does not depend on any other location—found infection site!
Example

```java
int low = 0;
int high = array.length - 1;
int mid;
while ( low <= high ) {
    mid = (low + high)/2;
    if ( target < array[mid] ) {
        high = mid - 1;
    } else if ( target > array[mid] ) {
        low = mid + 1;
    } else {
        return mid;
    }
}
return -1;
```
After Fixing the Defect

- Failures that exhibited a defect become new test cases after the fix
  - used for regression testing
- Use existing unit test cases to
  - test a suspected method in isolation
  - make sure that your bug fix did not introduce new bugs
  - exclude wrong hypotheses about the defect
Open Questions

1. How is evaluation of test runs related to specification?
   So far: wrote oracle program or evaluated interactively
   How to check automatically whether test outcome conforms to spec?

2. It is tedious to write test cases by hand
   Easy to forget cases
   Java: aliasing, run-time exceptions

3. When does a program have no more bugs?
   How to prove correctness without executing $\infty$ many paths?
